## Quasigroups

A *quasigroup*  $(Q, \cdot)$  is a set Q with a binary operation  $\cdot$  such that for each  $a, b \in Q$ , the equations

$$ax = b$$
 and  $ya = b$ 

have unique solutions  $x, y \in Q$ .

Multiplication tables of finite quasigroups = latin squares

(ロ) (同) (三) (三) (三) (○) (○)

### Loops

A *loop* is a quasigroup with an identity element  $1 \cdot x = x \cdot 1 = x$ .

Multiplication tables of loops = reduced Latin squares

	1	2	3	4	5
	2	1	4	5	3
Example:	3	4	5	1	2
	4	5	2	3	1
	5	3	1	2	4

< □ > < 同 > < Ξ > < Ξ > < Ξ > < Ξ < </p>

This is evidently not a group table. (Exercise)

## **Multiplication Group**

In a quasigroup Q, the left and right translations

 $L_x: Q \rightarrow Q; \quad yL_x = xy \qquad R_x: Q \rightarrow Q; \quad yR_x = yx$ 

are permutations.

The *multiplication group* of *Q* is generated by all of these:

$$\operatorname{Mlt}(Q) = \langle L_X, R_X \mid x \in Q \rangle.$$

(Think of the group generated by all rows and all columns of the corresponding latin square.)

Multiplication groups give a lot of information about loops, but do not determine them (e.g.  $Mlt(D_8) \cong Mlt(Q_8)$ ).

# Normality

An equivalence relation  $\theta$  on a quasigroup Q is a congruence if and only if its equivalence classes form a block system for Mlt(Q)

< □ > < 同 > < Ξ > < Ξ > < Ξ > < Ξ < </p>

# Normality

An equivalence relation  $\theta$  on a quasigroup Q is a congruence if and only if its equivalence classes form a block system for Mlt(Q)

Congruences on a loop Q are determined by *normal subloops*: A subloop  $A \subseteq Q$  is a congruence class of the identity element 1 if and only if it is a block of Mlt(Q) containing 1.

(ロ) (同) (三) (三) (三) (○) (○)

# Normality

An equivalence relation  $\theta$  on a quasigroup Q is a congruence if and only if its equivalence classes form a block system for Mlt(Q)

Congruences on a loop Q are determined by *normal subloops*: A subloop  $A \subseteq Q$  is a congruence class of the identity element 1 if and only if it is a block of Mlt(Q) containing 1.

A useful way of proving normality for a subloop:

If K is a normal subgroup of Mlt(Q), then  $A := 1^{K}$  is a normal subloop of Q.

(Conversely, every normal subloop is the orbit of 1 for some normal subgroup of Mlt(Q), but we won't need this.)

## Nuclei

The *left, middle* and *right nuclei* of a loop *Q* are the sets

$$Nuc_{\ell}(Q) = \{a \in Q \mid ax \cdot y = a \cdot xy, \forall x, y \in Q\}$$
$$Nuc_{m}(Q) = \{a \in Q \mid xa \cdot y = x \cdot ay, \forall x, y \in Q\}$$
$$Nuc_{r}(Q) = \{a \in Q \mid xy \cdot a = x \cdot ya, \forall x, y \in Q\}$$

◆□▶ ◆□▶ ◆ □▶ ◆ □▶ ● □ ● ● ● ●

## Nuclei

The *left, middle* and *right nuclei* of a loop *Q* are the sets

$$Nuc_{\ell}(Q) = \{a \in Q \mid ax \cdot y = a \cdot xy, \ \forall x, y \in Q\}$$
$$Nuc_{m}(Q) = \{a \in Q \mid xa \cdot y = x \cdot ay, \ \forall x, y \in Q\}$$
$$Nuc_{r}(Q) = \{a \in Q \mid xy \cdot a = x \cdot ya, \ \forall x, y \in Q\}$$

The nucleus is the intersection of these:

$$\operatorname{Nuc}(Q) = \operatorname{Nuc}_{\ell}(Q) \cap \operatorname{Nuc}_{m}(Q) \cap \operatorname{Nuc}_{r}(Q).$$

Each of the three nuclei (and hence the nucleus) is a subloop.

None of the nuclei need be normal, though in "nice" classes of loops, one or more of them often is.

The best known class of loops are *Moufang loops*. They are defined by any one of the following identities:

$$(xy)(zx) = x((yz)x)$$
$$((xy)x)z = x(y(xz))$$
$$((zx)y)x = z(x(yx))$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへぐ

Modulo CFSG, finite simple Moufang loops have been classified: they are groups or loops in a particular infinite family.

Moufang loops are often thought of as being the most "group-like" of loops.

## **Bol loops**

The 2nd best known class are *(left) Bol loops*, defined by the following identity:

$$(x(yx))z = x(y(xz))$$

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● のへぐ

*Right* Bol loops are defined dually.

## **Bol loops**

The 2nd best known class are *(left) Bol loops*, defined by the following identity:

$$(x(yx))z = x(y(xz))$$

▲□▶ ▲□▶ ▲ 三▶ ▲ 三▶ - 三 - のへぐ

Right Bol loops are defined dually. Left Bol + right Bol = Moufang.

## **Bol loops**

The 2nd best known class are *(left) Bol loops*, defined by the following identity:

$$(x(yx))z = x(y(xz))$$

*Right* Bol loops are defined dually. Left Bol + right Bol = Moufang.

**Example**: Let  $H^+(n, \mathbb{C})$  be the set of  $n \times n$  positive definite, hermitian matrices. For  $A, B \in H^+(n, \mathbb{C})$ , take the polar decomposition of AB:

$$AB = CU$$

where  $C \in H^+(n, \mathbb{C})$  and U is unitary. (In fact,  $C = (AB^2A)^{1/2}$ .) Define A \* B := C. Then  $(H^+(n, \mathbb{C}), *)$  is a left Bol loop.

In 1969, F. Fenyves observed that both Bol loops and Moufang loops were defined by identities with the same characteristics:

- They involve only the multiplication (no divisions).
- Three variables occur on each side of the equality, in the same order.
- One variable occurs twice on each side, the others only once.

(ロ) (同) (三) (三) (三) (○) (○)

Moufang loops: x((yz)x) = (xy)(zx) (and the other 2 equivalent identities)

(left) Bol loops: (x(yx))z = x(y(xz))

Fenyves decided to classify all such identities, which he referred to as identities of *Bol-Moufang type*, and to determine how many distinct varieties of loops they define.

(ロ) (同) (三) (三) (三) (○) (○)

Fenyves decided to classify all such identities, which he referred to as identities of *Bol-Moufang type*, and to determine how many distinct varieties of loops they define.

There are 60 such identities. It turns out that 30 of them are equivalent to associativity; for example, (xy)(yz) = ((xy)y)z.

(ロ) (同) (三) (三) (三) (○) (○)

(ロ) (同) (三) (三) (三) (○) (○)

In all, there are 14 distinct classes defined by identities of Bol-Moufang type.

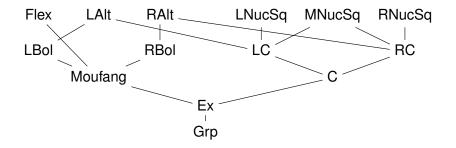

Fenyves decided to classify all such identities, which he referred to as identities of *Bol-Moufang type*, and to determine how many distinct varieties of loops they define.

There are 60 such identities. It turns out that 30 of them are equivalent to associativity; for example, (xy)(yz) = ((xy)y)z.

In all, there are 14 distinct classes defined by identities of Bol-Moufang type.

Fenyves completed almost all of the classification; he only missed a few inclusions, and gave very few examples to separate the classes. These holes were later filled in by Phillips and Vojtěchovský (2005).

## The 14 varieties

# **Defining Identities**

Flex I Alt RAIt Left Nuclear Squares Middle Nuclear Squares Right Nuclear Squares Left Bol **Right Bol** Left C Right C Moufang С Extra Groups

(xy)x = x(yx)(xx)y = x(xy)(xy)y = x(yy)(xx)(yz) = ((xx)y)z(x(yy)z) = x((yy)z)(xy)(zz) = x(y(zz))(x(yx))z = x(y(xz))((xy)z)y = x((yz)y)(xx)(yz) = (x(xy))z(xy)(zz) = x((yz)z)(xy)(zx) = x((yz)x)((xy)y)z = x(y(yz))((xy)z)x = x(y(zx))(xy)z = x(yz)

## Comments

- The strange names "extra" and "C" are due to Fenyves. No one knows exactly why he chose them.
- One guess is that he thought of "extra loops" as Moufang loops satisfying an "extra" condition (nuclear squares).
- It has been speculated that the somewhat uninspiring "C" is supposed to mean "central" (in the sense of middle, not in any algebraic sense), but as with "extra," there is no direct evidence in Fenyves' paper that this is what he had in mind.
- Anyway, there has been enough literature on these loops that we are stuck with the names.

# Normality of nuclei

right C	m = r	yes	dual

For the flexible, left alternative or right alternative varieties, nothing can be said. By themselves (or even together), they don't have enough structure to prove anything interesting.

What about left, middle or right nuclear squares? Again, each one alone has almost no structure. However...

# Main Result

Let

$$\operatorname{Nuc}_{\ell,m}(\mathcal{Q}) \coloneqq \operatorname{Nuc}_{\ell}(\mathcal{Q}) \cap \operatorname{Nuc}_m(\mathcal{Q}) \ \mathcal{G} \coloneqq \{L_a \mid a \in \operatorname{Nuc}_{\ell,m}(\mathcal{Q})\}$$

### Theorem

Let Q be a loop with left and middle nuclear squares. Then:

- G is a normal subgroup of Mlt(Q);
- **2** Nuc $_{\ell,m}(Q)$  is a normal subloop of Q.

Also true for:

- Loops with middle and right nuclear squares (duality)
- Loops with *left and right* nuclear squares (paratopy)

## Consequence

### Corollary

If Q is a loop with left and middle nuclear squares, then  $Q/\operatorname{Nuc}_{\ell,m}(Q)$  has exponent 2 ( $x^2 = 1$ ).

### Corollary

A simple loop with left and middle nuclear squares is a group or a loop of exponent 2.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ● ●

## What is needed

If  $a \in \operatorname{Nuc}_{\ell,m}(Q)$ , then for all  $x \in Q$ ,  $L_a R_x = R_x L_a$ .

Thus to show  $L_{(\operatorname{Nuc}_{\ell,m}(Q))}$  is normal in  $\operatorname{Mlt}(Q)$ , it is enough to show that it is normalized by each left translation  $L_x$ . In other words, we must show that for all  $x \in Q$ ,

$$L_x L_a L_x^{-1} = L_{(xa)/x}$$
$$L_x^{-1} L_a L_x = L_{x \setminus (ax)}$$

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

and that (xa)/x,  $x \setminus (ax) \in \operatorname{Nuc}_{\ell,m}(Q)$ .

## What is needed

If  $a \in \operatorname{Nuc}_{\ell,m}(Q)$ , then for all  $x \in Q$ ,  $L_a R_x = R_x L_a$ .

Thus to show  $L_{(\operatorname{Nuc}_{\ell,m}(Q))}$  is normal in  $\operatorname{Mlt}(Q)$ , it is enough to show that it is normalized by each left translation  $L_x$ . In other words, we must show that for all  $x \in Q$ ,

$$L_x L_a L_x^{-1} = L_{(xa)/x}$$
  
 $L_x^{-1} L_a L_x = L_{x \setminus (ax)}$ 

and that (xa)/x,  $x \setminus (ax) \in \operatorname{Nuc}_{\ell,m}(Q)$ .

*This is a purely equational problem!* Let us not waste our precious brain cells on it.

### Prover9

% loop  $1 * x = x \cdot x * 1 = x$ . (x \* y) / y = x. (x / y) \* y = x. $X \setminus (X * Y) = Y \cdot X * (X \setminus Y) = Y \cdot$ % left & middle nuclear squares ((X \* X) \* Y) \* Z = (X \* X) \* (Y \* Z).(X \* (Y \* Y)) \* Z = X \* ((Y \* Y) \* Z).% a in left & middle nucleus (a \* x) \* y = a \* (x \* y).(x \* a) \* y = x \* (a \* y).% goals  $x \setminus (a * (x * y)) = (x \setminus (a * x)) * y.$  $x * (a * (x \setminus y)) = ((x * a) / x) * y.$

I come down somewhere between these. For very long proofs, the Law of Diminishing Returns kicks in as to whether or not humanization is worthwhile. Otherwise it is worth trying.

"Humanization" does not just mean doing a line-by-line literal translation of the proof. It means writing a proof for human consumption that uses existing theory to simplify steps and then identifies new key steps.

There are different attitudes about how to react once an automated theorem prover succeeds in finding a proof:

I come down somewhere between these. For very long proofs, the Law of Diminishing Returns kicks in as to whether or not humanization is worthwhile. Otherwise it is worth trying.

"Humanization" does not just mean doing a line-by-line literal translation of the proof. It means writing a proof for human consumption that uses existing theory to simplify steps and then identifies new key steps.

In this case, the Prover9 proofs were reasonably short (a few hundred steps), so it was straightforward to humanize them.

## Loops with central squares

Finally, consider loops with *central* squares: Nuclear squares + commuting squares:  $x^2y = yx^2$ .

#### Lemma

The following are equivalent in a loop with central squares:

• Automorphic inverse property (AIP):  $(xy)^{-1} = x^{-1}y^{-1}$ ;

(日) (日) (日) (日) (日) (日) (日)

• Endomorphic squaring (ES):  $(xy)^2 = x^2y^2$ .

# Decomposition

### Theorem

Let Q be a loop with squares in two nuclei. If Q has AIP or ES, then it has central squares (hence both AIP and ES).

#### Theorem

Let Q be a finite loop with squares in two nuclei and AIP/ES. Then

$$Q \cong E \times O$$

#### where

- E is a loop in which every element has order a power of 2, and
- O is a loop of odd order.

Now let's have coffee!
